(Received 17 May 2014; revised manuscript received 22 September 2014; published 7 January 2015)

We present angle-resolved photoemission studies on the rare-earth-hexaboride YbB$_6$, which has recently been predicted to be a topological Kondo insulator. Our data do not agree with the prediction and instead show that YbB$_6$ exhibits a novel topological insulating state in the absence of a Kondo mechanism. We find that the Fermi level electronic structure of YbB$_6$ has three 2D Dirac cone like surface states enclosing the Kramer’s points, while the f orbital that would be relevant for the Kondo mechanism is ~1 eV below the Fermi level. Our first-principles calculation shows that the topological state that we observe in YbB$_6$ is due to an inversion between Yb d and B p bands. These experimental and theoretical results provide a new approach for realizing novel correlated topological insulator states in rare-earth materials.

DOI: 10.1103/PhysRevLett.114.016403 PACS numbers: 71.20.Eh, 73.20.At

Rare-earth materials are interesting because the strong electronic correlation in their f electrons leads to novel ground states such as a Kondo insulating state, valence fluctuation state, and heavy fermion superconductivity state [1–4]. Among these correlation-driven ground states, Kondo insulators are characterized by a particularly narrow band gap (on the order of 10–40 meV) at low temperatures with the chemical potential in the gap. Unlike typical band insulators the energy gap that opens up at low temperatures in a Kondo insulator is in fact due to the Kondo hybridization of localized f electrons with conduction electrons [1–4]. Since the advent of topological insulators [5–11], recently the rare-earth Kondo insulator SmB$_6$ has attracted much interest due to the theoretical prediction that it exhibits a topological Kondo insulator (TKI) phase [12–14]. In a TKI, the Kondo hybridization between the d and f bands further leads to an inversion of the band parity, and therefore realizes a topologically nontrivial insulator phase. Following the theoretical predictions, photoemission and transport experiments have identified the existence of an odd number of in-gap surface states and a two-dimensional conductance channel at low temperatures in SmB$_6$ [15–21], consistent with the theoretically predicted TKI phase. However, the surface states in the TKI phase of SmB$_6$ only exist at very low temperatures [16] and their Fermi velocity is expected to be low due to a strong f-orbital contribution [14,16], limiting its future applications in devices.

In order to search for other novel correlated topological phases even without a Kondo mechanism, it is quite suggestive to systematically study other rare-earth materials that are closely related to SmB$_6$. SmB$_6$ belongs to a class of materials called the rare-earth hexaborides, RB$_6$ ($R =$ rare-earth metal). In general, rare-earth hexaboride compounds can have three types of electronic bands in the vicinity of the Fermi level, namely, the R 5d orbital band, the R 4f orbital band, and the boron 2p band. The low-energy physics for a rare-earth hexaboride is collectively determined by the relative energies between these bands and the Fermi level, which depends on a delicate interplay among the key physical parameters including the valence of the rare-earth element, the lattice constant, the spin-orbit coupling (SOC), etc. As a result, the rare-earth hexaborides can realize a rich variety of distinct electronic ground states such as the proposed TKI state in SmB$_6$, ferromagnetic order in EuB$_6$, and superconductivity in LaB$_6$ ($T_c$ ~ 0.5 K) [4,22,23].

Despite these interesting aspects, apart from SmB$_6$, experimental studies on the electronic ground states of RB$_6$ compounds are almost entirely lacking. In contrast to the Kondo insulator state in SmB$_6$, YbB$_6$ is known to be a doped semiconductor from transport experiments [22]. This difference is particularly interesting since SmB$_6$ and YbB$_6$ share many important properties such as the same crystal structure and the same sets of low-energy bands ($R$ 5d, $R$ 4f, and B 2p). Moreover, it is interesting to investigate whether the semiconducting state in YbB$_6$ can also host topological order and how that order is different from that in the TKI phase in SmB$_6$. Here, we report systematic studies on the electronic ground state of YbB$_6$. We show
that unlike in SmB₆, the lowest f orbital in YbB₆ is about 1 eV away from the Fermi level, suggesting the near absence of Kondo insulating behavior in contrast to the well known mixed-valence system SmB₆. Our spectroscopic data show that the Fermi level of YbB₆ features nearly linearly dispersive states without observable out-of-plane momentum k_z dispersion. Guided by the systematic experimental data, we present new band calculations with an adjustable correlation parameter (Hubbard U), which reveal that the observed topological state in YbB₆ is due to a band inversion between the d and p bands under a nonzero Coulomb interaction value.

Single crystal samples of YbB₆ were grown in the Fisk lab at the University of California (Irvine) by the AI-flux method, which is detailed elsewhere [18,22]. Synchrotron-based angle-resolved photoemission spectroscopy (ARPES) measurements of the electronic structure were performed at the PGM beamline of the Synchrotron Radiation Center, Stoughton, Wisconsin and Beamline 10.0.1 of the Advanced Light Source, Berkeley, California equipped with high-efficiency Scienta R4000 electron analyzers. The energy resolution was 10–30 meV and the angular resolution was better than 0.2° for all synchrotron measurements. The samples were cleaved along the (001) plane and were measured in ultrahigh vacuum better than 10⁻¹⁰ Torr. The first-principles bulk band calculations were performed based on the generalized gradient approximation (GGA) [24] using the projector augmented-wave method [25,26] as implemented in the VASP package [27,28]. The experimental crystallographic structure was used [29] for the calculations. The spin-orbit coupling was included self-consistently in the electronic structure calculations with a 12 × 12 × 12 Monkhorst-Pack k mesh. The surface electronic structure computation was performed with a symmetric slab with a thickness of 24 unit cells.

YbB₆ shares the same CsCl type of crystal structure with SmB₆, as shown in Fig. 1(a). The bulk Brillouin zone (BZ) is cubic, where the center of the BZ is the Γ point and the center of each face is the X point. It is known from theoretical calculations [4] that three different atomic orbitals contribute to the low-energy electronic structure, namely the the rare-earth 5d orbital band, the rare-earth 4f orbital band, and the boron 2p band. Both the valence band maximum and the conduction band minimum are around the X point [4]. A variety of electronic ground states can be realized due to the delicate interplay of the relative energy levels among these bands and the Fermi level. For example, the left panel of Fig. 1(e) shows a condition for the Kondo insulator state, as observed in SmB₆. The R 5d and R 4f bands cross each other near the Fermi level, whereas the B 2p band lies energetically below the 5d and 4f bands, and therefore is irrelevant to the low-energy physics. At low temperatures, the itinerant 5d electrons hybridize with the localized 4f electrons and open up a Kondo energy gap, which leads to the Kondo insulating state. On the other hand, the right panel of Fig. 1(e) presents a different scenario, where the R 4f band resides far away from the Fermi level. In this case, the R 5d and B 2p bands dominate the low-energy physics, and they can even show a finite band inversion depending on the details of the material parameters. In order to reveal the electronic state of YbB₆, we systematically study its electronic structure at the (001) natural cleavage surface. Figure 1(c) shows the momentum-integrated photoemission spectrum over a wide binding energy window. The Yb 4f and Yb 5p core levels are clearly observed. To more precisely determine the energy positions of the Yb 4f with respect to the Fermi level, we present a k-resolved dispersion map. As clearly seen in Fig. 1(d), the lowest 4f flat band in YbB₆ is 1 eV below the Fermi energy [30]. This is in sharp contrast to the ARPES data on SmB₆, where the flat 4f band is found to be only <15 meV away from the Fermi level [16]. Therefore, our data reveal the physical origin for the absence of the Kondo insulating state in YbB₆, which also negates the recent theoretical work that predicts the existence of the topological Kondo insulator phase in YbB₆ [23]. Apart from the intense 4f band, our data in Fig. 1(d) also reveal an electronlike pocket centered at the X point that crosses the Fermi level.

In order to systematically resolve the Fermi level electronic structure, in Figs. 2 and 3 we present high-resolution ARPES measurements in the close vicinity...
of the Fermi level. It is important to note that at the studied (001) surface, the three \(X\) points (\(X_1\), \(X_2\), and \(X_3\)) in the bulk BZ project onto the \(\bar{\Gamma}\) point and the two \(\bar{X}\) points on the (001) surface BZ, respectively. Since the valence band maximum and conduction band minimum are at the \(X\) points, at the (001) surface one would expect low-energy electronic states near the \(\bar{\Gamma}\) point and \(\bar{X}\) points. The Fermi surface map of YbB\(_6\) is presented in Fig. 2(a). Our Fermi surface map reveals multiple pockets, which consist of an oval-shaped contour and a nearly circular-shaped contour enclosing each \(X\) and \(\bar{\Gamma}\) points. No pocket is seen around the \(\bar{M}\) point. YbB\(_6\) shows metallic behavior in transport [22], which is consistent with our data.

We present ARPES energy and momentum dispersion maps, where low-energy states consistent with the observed Fermi surface topology are clearly identified. As shown in Fig. 2(b), a \(V\)-shaped linearly dispersing band is observed at each of the \(\bar{\Gamma}\) and \(\bar{X}\) points. We further study the photon energy dependence of the observed \(V\)-shaped bands. As shown in Figs. 2(b) and 3(a), the \(V\)-shaped bands are found to show no observable dispersion as the incident photon energy is varied, which suggests its two-dimensional nature. Therefore, our systematic ARPES data have identified three important properties in the YbB\(_6\) electronic structure: (1) An odd number of Fermi surface pockets is observed to enclose the Kramers’ point. (2) The bands at the Fermi level are found to exhibit nearly linearly (Dirac-like) in-plane dispersion; (3) No observable out-of-plane (\(k_z\)) dispersion is observed for these Dirac-like (\(V\)-shaped) bands. All these properties that we observed are consistent with a topological insulator state in YbB\(_6\). We also find that the Dirac surface states are robust to the rise of temperatures, see Fig. 3(b). This contrasts sharply with the in-gap states observed in SmB\(_6\), which are observed to disappear above ~30 K [16]. Our systematic data are consistent with two other concurrent ARPES studies on YbB\(_6\) [31,32].

In order to better understand the electronic structure that we observe in ARPES, we perform first-principles calculations on the bulk band structure of YbB\(_6\) using the GGA + SOC + \(U\) method. Our ARPES data shown here negate the predicted topological Kondo insulator state in a previous calculation result [23]. Thus, there is no theoretical calculation that can reproduce the novel topological insulator state in YbB\(_6\) revealed by our ARPES data.

FIG. 2 (color online). Fermi surface and dispersion map. (a) ARPES measured Fermi surface of YbB\(_6\). Circular-shaped pockets are observed at \(\bar{\Gamma}\) and \(\bar{X}\) points. It is measured with a photon energy of 50 eV at a temperature of 15 K. (b) ARPES dispersion maps measured with different photon energy. The measured photon energies are noted on the plots. These data were collected at ALS BL10.

FIG. 3 (color online). Photon energy and temperature dependent dispersion maps (a) Photon energy dependent dispersion map with wider binding energy. The measured photon energies are noted on the plots. The \(4f\) flat bands are about 1 eV below the Fermi level. These spectra are measured along the \(\bar{\Gamma}-\bar{X}\) momentum-space cut direction with a temperature of 15 K. These data were collected at the SRC PGM beamline. (b) Temperature dependent ARPES spectra. The measured temperatures are noted on the plots. These spectra are measured along the \(\bar{\Gamma}-\bar{X}-\bar{\Gamma}\) momentum-space cut at ALS BL10.0.1.
(also the two occurant ARPES studies [31,32]). Here, we present new band calculations with an adjustable correlation parameter (Hubbard $U$). Figures 4(a) and 4(b) show the calculated YbB$_6$ bulk band structure obtained by using various on-site $U$ values for the Yb $4f$ orbitals. For $U = 0$, our calculation shows that the Yb $4f$ orbital is located very close to the Fermi level and crosses the Yb $5d$ band. This is inconsistent with our data, which clearly show that the lowest $4f$ band is 1 eV away from the Fermi level and does not cross the Yb $5d$ conduction band. We study the calculated band structure with nonzero $U$ values. Figure 4(b) shows the calculation for $U = 4$ eV. Interestingly, it can be seen that the Yb $4f$ band is moved toward higher energies away from the Fermi level as one increases $U$. For $U = 4$ eV, the $4f$ band moves to a higher energy and does not cross the $5d$ band, which agrees with our data. Furthermore, the B $2p$ band is “pushed” toward the Fermi level and forms a holelike valence band, also consistent with our data. A finite band inversion between the Yb $5d$ and B $2p$ bands is obtained from our calculation for $U = 4$ eV. Spin-orbit coupling opens a finite (inverted) energy gap, leading to an inversion of the parity eigenvalues at the $X$ point between the $d$ and $p$ bands [30]. We conducted a surface (slab) electronic structure calculation for the Coulomb interaction value $U = 4$ eV, where a $d$-$p$ band inversion is seen. As shown in Fig. 4(c), our slab calculation clearly shows topological Dirac surface states at both the $\bar{\Gamma}$ and $\bar{X}$ points. We note that the observed small gap at the $\bar{X}$ point is a quantum tunneling gap due to the finite size effect [30]. Furthermore, the $4f$ bands are far away from the Fermi level and hence the Kondo mechanism is irrelevant. These systematic calculations, for the first time, reveal that the experimentally observed topological state in YbB$_6$ is due to a bulk band inversion between the $d$ and $p$ bands under a nonzero Coulomb interaction value.

In conclusion, by using high-resolution ARPES we show that, unlike SmB$_6$, the lowest $f$ orbital in YbB$_6$ is about 1 eV away from the Fermi level, which reveals that it is not a TKI. Our data show that the Fermi level of YbB$_6$ features linearly dispersive bands without observable out-of-plane $k$ dispersion. These bands are found to form odd Fermi surface pockets enclosing the Kramers’ points per BZ. We provide a theoretical calculation that reveals a novel topological insulator state due to band inversions between the Yb $5d$–B $2p$ orbitals, which is consistent with our data. Our results provide a new approach for realizing a topological insulator in rare-earth hexaborides even without considering the Kondo mechanism.
